SCOP: Structural Classification of Proteins

Current release: 1.71
27599 PDB Entries (October 2006). 75930 Domains.

<http://scop.mrc-lmb.cam.ac.uk/scop/>

The **SCOP** database aims to provide a detailed and comprehensive description of the structural and evolutionary relationships between all proteins whose structure is known. Proteins are classified to reflect both structural and evolutionary relatedness. Many levels exist in the hierarchy; the principal levels are family, superfamily and fold

Family: *Clear evolutionarily relationship*

Superfamily: *Probable common evolutionary origin*

Fold: *Major structural similarity*

SCOP: Structural Classification of Proteins

Family: *Clear evolutionarily relationship*

Proteins clustered together into families are clearly evolutionarily related. Generally, this means that pairwise residue identities between the proteins are 30% and greater. However, in some cases similar functions and structures provide definitive evidence of common descent in the absence of high sequence identity; for example, many globins form a family though some members have sequence identities of only 15%.

SCOP: Structural Classification of Proteins

Superfamily: Probable common evolutionary origin

Proteins that have low sequence identities, but whose structural and functional features suggest that a common evolutionary origin is probable are placed together in superfamilies. For example, actin, the ATPase domain of the heat shock protein, and hexokinase together form a superfamily.

SCOP: Structural Classification of Proteins

Fold: Major structural similarity

Proteins are defined as having a common fold if they have the same major secondary structures in the same arrangement and with the same topological connections. Different proteins with the same fold often have peripheral elements of secondary structure and turn regions that differ in size and conformation. In some cases, these differing peripheral regions may comprise half the structure. Proteins placed together in the same fold category may not have a common evolutionary origin: the structural similarities could arise just from the physics and chemistry of proteins favoring certain packing arrangements and chain topologies.

SCOP Statistics

Class	Folds	Super families	Families
All alpha proteins	179	299	480
All beta proteins	126	248	462
Alpha and beta proteins (a/b)	121	199	542
Alpha and beta proteins (a+b)	234	349	567
Multi-domain proteins	38	38	53
Membrane and cell surface proteins	36	66	73
Small proteins	66	95	150
Total	800	1294	2327

FSSP Database

Current release: September 2005

3724 sequence families representing 30624 protein structures

The FSSP database is based on exhaustive all-against-all 3D structure comparison of protein structures currently in the Protein Data Bank (PDB). The classification and alignments are automatically maintained and continuously updated using the Dali search engine.

Structure processing for Dali/FSSP

Adopted from Holm and Sander, 1998

Dali Domain Dictionary

<http://www2.ebi.ac.uk/dali/domain>

Structural domains are delineated automatically using the criteria of recurrence and compactness. Each domain is assigned a Domain Classification number DC_l_m_n_p, where:

- l - fold space attractor region
- m - globular folding topology
- n - functional family
- p - sequence family

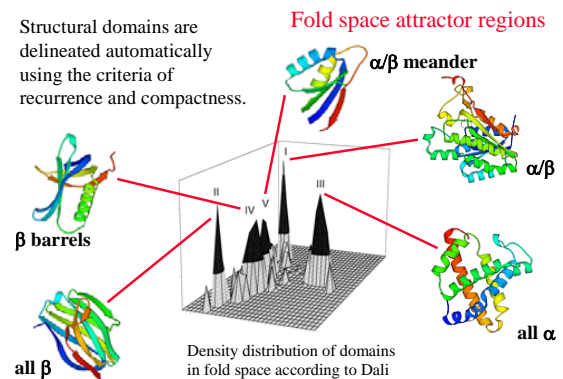

Hierarchical clustering of folds in Dali/FSSP

Adopted from Holm and Sander, 1998

Dali Domain Dictionary

Structural domains are delineated automatically using the criteria of recurrence and compactness.

Dali Domain Dictionary

Fold types

Fold types are defined as clusters of structural neighbors in fold space with average pairwise Z-scores (by Dali) above 2.

Structural neighbours of IurnA (top left). Imli (bottom right) has the same topology even though there are shifts in the relative orientation of secondary structure elements

Dali Domain Dictionary

Functional families

The third level of the classification infers plausible evolutionary relationships from strong structural similarities which are accompanied by functional or sequence similarities. Functional families are branches of the fold dendrogram where all pairs have a high average neural network prediction for being homologous. The neural network weighs evidence coming from: overlapping sequence neighbours as detected by PSI-Blast, clusters of identically conserved functional residues, E.C. numbers, Swissprot keywords.

Dali Domain Dictionary

Sequence families

The fourth level of the classification is a representative subset of the Protein Data Bank extracted using a 25 % sequence identity threshold. All-against-all structure comparison was carried out within the set of representatives. Homologues are only shown aligned to their representative.

CATH - Protein Structure Classification

Current release: 3.1.0 (January 2007)

http://www.biochem.ucl.ac.uk/bsm/cath_new/

CATH is a novel hierarchical classification of protein domain structures, which clusters proteins at four major levels:

- C**lass
- A**rchitecture
- T**opology
- H**omologous superfamily

CATH - Protein Structure Classification

CATH - Protein Structure Classification

Class, C-level

Class is determined according to the secondary structure composition and packing within the structure. It can be assigned automatically (90% of the known structures) and manually.

Three major classes:

- mainly-alpha
- mainly-beta
- alpha-beta (alpha/beta and alpha+beta)

A fourth class is also identified which contains protein domains which have low secondary structure content.

CATH - Protein Structure Classification

Architecture, A-level

This describes the overall shape of the domain structure as determined by the orientations of the secondary structures but ignores the connectivity between the secondary structures.

It is currently assigned manually using a simple description of the secondary structure arrangement e.g. barrel or 3-layer sandwich. Reference is made to the literature for well-known architectures (e.g. the beta-propeller or alpha four helix bundle).

Procedures are being developed for automating this step.

CATH - Protein Structure Classification

Topology (Fold family), T-level

Structures are grouped into fold families at this level depending on both the overall shape and connectivity of the secondary structures. This is done using the structure comparison algorithm SSAP.

Some fold families are very highly populated and are currently subdivided using a higher cutoff on the SSAP score.

CATH - Protein Structure Classification

Homologous Superfamily, H-level

This level groups together protein domains which are thought to share a common ancestor and can therefore be described as homologous. Similarities are identified first by sequence comparisons and subsequently by structure comparison using SSAP.

Structures are clustered into the same homologous superfamily if they satisfy one of the following criteria:

- Sequence identity $\geq 35\%$, 60% of larger structure equivalent to smaller
- SSAP score ≥ 80.0 and sequence identity $\geq 20\%$ 60% of larger structure equivalent to smaller
- SSAP score ≥ 80.0 , 60% of larger structure equivalent to smaller, and domains which have related functions

CATH - Protein Structure Classification

Sequence families, S-level

Structures within each H-level are further clustered on sequence identity. Domains clustered in the same sequence families have sequence identities $>35\%$ (with at least 60% of the larger domain equivalent to the smaller), indicating highly similar structures and functions.

CATH Statistics

Version 3.1.0 Date 19-01-2007

Number of Domains 93,885

Classification limitations

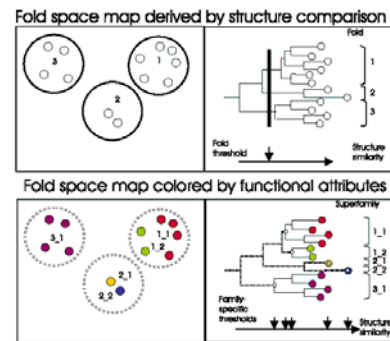

Adopted from Getz et al., 2002

Classification limitations

Homologous and Analogous Proteins

Adopted from Dietmann & Holm, 2001

Homologous and Analogous Proteins

- Homologous: same fold, same or similar function, common ancestry.

- Analogous: same fold, different function, ancestral origin unknown.
